Induced Raman Scattering in Pulsar Magnetospheres

Maxim Lyutikov

Theoretical Astrophysics, California Institute of Technology, Pasadena, California 91125, USA [1]

ABSTRACT

It is shown that induced Raman scattering of electromagnetic waves in the strongly magnetized electron-positron plasma of pulsar magnetosphere may be important for wave propagation and as an effective saturation mechanism for electromagnetic instabilities. The frequencies, at which strong Raman scattering occurs in the outer parts of magnetosphere, fall into the observed radio band. The typical threshold intensities for the strong Raman scattering are of the order of the observed intensities, implying that pulsar magnetosphere may be optically thick to Raman scattering of electromagnetic waves.

1. Introduction

We aim to estimate the effects of the the induced Raman scattering of the strong electromagnetic wave propagating in pulsar magnetosphere. Raman scattering may be considered as a parametric decay of the initial transverse electromagnetic wave in the another electromagnetic wave and plasma wave. The probability of this process is greatly enhanced if there many waves present in the final states. This is induced Raman scattering. Another type of induced scattering - induced Brullion scattering, i.e. the decay of the initial transverse electromagnetic wave in the another electromagnetic wave and ion sound is prohibited in electron-positron plasma, since pair plasma does not support low frequency, density perturbing waves (like ion sound wave in electron-ion plasma).

Strong nonlinear coupling occurs when two waves beat together and the sum or difference frequency and wavelength match the frequency and wavelength of the third wave:

$$\begin{aligned} \omega_3 &= \omega_1 + \omega_2 \\ k_{z,3} &= k_{z,1} + k_{z,2} \end{aligned} \tag{1}$$

In quantum language these relations may be interpreted as conservation of energy and momentum along the magnetic field, respectively. (the transverse components of the momentum are not conserved). The probability of the induced scattering depends on the number of waves in the final state, which, in turn, depends on the damping or escape rate of the daughter waves. The energy transfer between the modes will be efficient if the energy of the pump wave is strong enough to overcome the damping losses or escape of the generated waves. Thus, the induced Raman scattering is a threshold process: if the intensity of the pump wave exceeds the threshold value, the initial electromagnetic wave would start converting energy into the decay waves decreasing its amplitude exponentially.

Induced Raman scattering may be important in the pulsar environment in two ways. First, it may provide en effective damping of the existing electromagnetic wave, that has been generated by some emission mechanism at the lower altitude in the pulsar magnetosphere, where the resonant conditions for the induced Raman scattering were not satisfied. This may result in a short time variability which is generally observed in pulsar radio emission. Secondly, it may provide an effective saturation mechanism for the growth of the electromagnetic wave provided that the conditions for the wave excitation by some mechanism are satisfied in the region where an effective Raman scattering takes place.

The first possibility, i.e. the scattering of the existent wave, is simpler to consider. As a first approximation, we can treat the intensity of the pump wave as a constant. Then the nonlinear equations describing the wave coupling become linear in amplitudes of the decayed waves. The exponentially growing solutions will imply an effective energy transfer from the pump wave. As the intensities of the decay waves grow, this approximation breaks down in two cases: when the amplitudes of the decay waves become comparable to the pump wave or when the amplitude of the decay waves enter nonlinear stage and the waves start loosing energy due to some nonlinear process (like particle trapping and acceleration). The net effect of any energy loss by the decay wave is the depletion of the original pump wave. For the practical estimates, we can neglect the nonlinear stages of evolution (like cyclic energy transfer between the pump and the daughter waves) and assume that if the intensity of the pump wave begins to decrease exponentially in the linear stage, then the wave decays completely.

The second possibility, e.g. when the induced Raman scattering provides a nonlinear saturation mechanism, is more complicated, since the intensities of all waves may be of the same order. A considerable simplification in this case may be obtained if the damping of one of the decay modes is very strong or if it leaves the region of the resonant interaction fast enough. Then, after a short period of time (when the intensities of the other weakly damped waves grow considerably) the intensity of this damped mode is much smaller than the intensities of the two other modes and can be neglected.

In what follows we neglect the possible nonlinear stages of the development of Langmuir turbulence (particle trapping or quasilinear diffusion). We also assume that the pump wave is broadband. This is quite different from the conventional laboratory case of a monochromatic laser-plasma interaction. The condition of a broadband pump wave implies that its band width $\Delta\omega$ is much larger than the typical growth rate of the decay instability Γ:

$$\Delta\omega \gg \Gamma \tag{2}$$

If this condition is satisfied, then we can use a random phase approximation for the statistical description of the interacting waves. On the other hand, the condition of weak turbulence allows one to calculate the matrix elements of the interaction in the approximation of stationary phases.

The general expression for the third order nonlinear current in plasma in a magnetic field has been written down by Tsytovich & Shvartsburg 1965. An extremely complicated form of the corresponding expressions makes the general case of Raman scattering very difficult to consider. Several important simplifications can be done when considering induced Raman scattering in the pulsar magnetosphere. First, the superstrong magnetic field allows an expansion of the currents in $1/\omega_B$. Second, in the pair plasma with the same distributions of electrons and positrons some of the nonlinear currents cancel out since they are proportional to the third power of the electric charge (this cancellation is exact in the unmagnetized electron-positron plasma). The third, less justified approximation, is that we will make is that all the three interacting waves propagate along magnetic field. This is an important assumption. It allows us to simplify the consideration considerably and to obtain some analytical estimates of the effects of induced Raman scattering.

A short overview of the work on the nonlinear process in the pulsar magnetosphere will be appropriate here. The possible decay processes for the transverse waves and the corresponding references are (t denotes transverse wave, l denotes longitudinal wave and e denotes a charged particle): (i) a decay of a transverse wave into two transverse wave $t \rightarrow t' + t''$ (Gedalin & Machabeli 1982), (ii) a decay of a transverse wave into two Lagmiur waves $t \rightarrow l + l'$ (Gedalin & Machabeli 1983), (iii) a decay of a transverse wave into another transverse and Lagmuir wave $t \rightarrow t' + l$ (Gedalin & Machabeli 1983) [1] (iv) induced scattering of transverse waves $t + e \rightarrow t' + e$ (Blandford & Scharlemann 1976, Sincell & Krolik 1992, Ochelkov & Usov 1983, Wilson 1982). The possible processes for Lagmuir waves are (i) a decay of a Lagmuir wave into another Lagmuir and transverse wave $l \rightarrow t + l'$ (Gedalin & Machabeli 1983), (ii) a decay of a Lagmuir wave into two transverse waves $l \rightarrow t + t'$ (Mikhailovski 1980), (iii) Lagmuir wave merger $l + l' \rightarrow t$ (Mamradze, Machabeli & Melikidze 1980), (iii) induced scattering of Lagmuir waves (Lyubarskii 1993). When treating the nonlinear process involving transverse waves, the matrix elements in above works have been calculated in the drift approximation - the expansion in parameter $1/\omega_B$ was done in the very beginning ($\omega_B = |q|B/mc$ is the positive nonrelativistic cyclotron frequency, B is magnetic field, m is mass of an electron and c is the speed of light).

2. Kinematics of Raman Scattering in Pair Plasma

2.1. Wave dispersion

Normal modes of relativistic pair plasma for the case of parallel propagation consist of two transverse waves with the dispersion relation

$$\omega = kc(1-\delta), \quad \delta = \frac{\omega_p^2 T_p}{\omega_B^2} \tag{3}$$

---

[1] The final answer for the matrix element contains probably an insignificant typographical error

and a plasma Langmuir wave with a dispersion relation

$$\omega^2 = \frac{2\,\omega_p^2}{T_p} + k^2 c^2 \beta_T^2 \tag{4}$$

where in Eq. (4) the wave vectors should not be much larger than cross-over point:

$$\omega_o^2 = k_o^2 c^2 = 2\omega_p^2 < \gamma(1+\beta)^2 > \tag{5}$$

(Lyutikov 1998). We have introduced here a plasma frequency in the plasma frame $\omega_p^2 = 2\omega_B \Omega \lambda / \gamma_p$, where Ω is the pulsar rotation angular velocity, λ is the multiplicity factor, γ_p is the Lorentz factor of the plasma frame, $T_p \approx < \gamma >$ is Lorentz invariant temperature of plasma, γ is Lorentz factor of a particle and $\beta_T = \sqrt{T_p^2 - 1}/T_p$ is a characteristic (dimensionless) thermal velocity of particles, β is (dimensionless) velocity. The brackets denote averaging over the distribution function.

At the point $\{\omega_o, k_o\}$ the dispersion curve of plasma waves intersect that of waves in vacuum, so that for $k > k_o$ the plasma waves become subluminous. The necessary requirement for that is that the distribution function falls fast enough at large values of momentum (faster than $1/p^4$) (Lominadze & Mikhailovskii 1978).

In the subluminous region, the plasma wave dispersion relation may be written as

$$\begin{aligned} &\omega = kc - \eta(k - k_o)c, \qquad \text{where} \\ &\eta = 1 - \left(\frac{\partial \epsilon_{zz}}{\partial k}\right) \Big/ \left(\frac{\partial \epsilon_{zz}}{\partial \omega}\right)\Big|_{\omega_o, k_o} = \frac{< \gamma(1+\beta)^2 >}{< \gamma^3(1+\beta)^3 >} \approx \frac{1}{T_p^2} \end{aligned} \tag{6}$$

2.2. Scattered frequencies

From the resonant conditions

$$\begin{aligned} \omega_3 &= \omega_1 + \omega_2 \\ k_3 &= k_1 + k_2 \end{aligned} \tag{7}$$

it follows that that the only kinematically allowed Raman scattering process is a back scattering ($k_1 < 0$) of the initial electromagnetic wave (see Fig. 1). We find then

$$\begin{aligned} k_3 &= \frac{1}{2c}\left(\frac{\omega_2}{1-\delta} + k_2\, c\right) \\ |k_1| &= \frac{1}{2c}\left(-\frac{\omega_2}{1-\delta} + k_2\, c\right) \end{aligned} \tag{8}$$

In the region just above the cross-over point $\{\omega_o, k_o\}$ it is possible to use the expansion (6) for the dispersion of the plasma waves. The resonant wave vectors are then given by

$$k_3 = \frac{k_2 + k_o}{2}\left(1 - \frac{k_2 - k_o}{4T^2 k_o}\right), \qquad |k_1| = \frac{k_2 - k_o}{2} \tag{9}$$

The wave vectors in Eq. (9) are limited by $k_2 - k_o \leq k_o$, $|k_1| \leq k_o$.

2.3. Induced Raman Versus Induced Compton Scattering

Induced Raman scattering is closely related to the induced Compton scattering of waves by the plasma particles. In the conventional treatment of induced Compton scattering in pulsar setting (e.g. Blandford & Scharlemann 1976, Sincell & Krolik 1992) the collective effects of the plasma are ignored. In the case of induced Raman scattering collective effects play a major role. Raman scattering is a limit of the induced Compton scattering of waves by particles in a medium when the beat wave of the incoming and scattered wave becomes a normal mode of the medium (equivalently, it falls on the "mass surface" of the medium dispersion equation).

In the nonrelativistic plasma the collective treatment of the wave scattering by plasma particles is justified if the following condition is true:

$$\Delta k \lambda_D \ll 1 \tag{10}$$

where Δk is the change in the wave number of the scattered wave and λ_D is the Debye length. Condition (10) states that the wave number of the oscillations of the electron on the beat of the two scattered waves be much less than the inverse of the Debye length. If condition (10) is not satisfied, then the beat wave will either experience a strong Cherenkov damping (if $\Delta k \lambda_D \approx 1$) or the beat wave will not feel the presence of a medium (if $\Delta k \lambda_D \gg 1$), so that the scattering process will be described as induced Compton scattering.

In the relativistic plasma with the characteristic Lorentz factor of the particles $< \gamma > \gg 1$ the condition (10) is modified. To find the the generalization of condition (10) to the case of relativistic plasma we note, that condition (10) may be rewritten in therm of the phase velocities of the beat wave $v_{ph} = \omega / k$ (which is a plasma wave in case of Raman scattering) and the thermal velocities of the plasma particles $v_T =< v^2 >^{1/2}$. Condition (10) then can be rewritten

$$v_{ph} \gg v_T \tag{11}$$

Using (6), we find that the phase velocity of the subluminous plasma waves becomes equal to the thermal velocity of plasma particles approximately at $k \approx 2k_o$. Thus, the following condition should hold for the wave-particles scattering in relativistic pair plasma to be considered as a Raman scattering:

$$\Delta k < 2k_o \approx 4\sqrt{2 < \gamma >} \omega_p \tag{12}$$

When $\Delta k \approx 2k_o$ the plasma waves are strongly damped and when $\Delta k \gg 2k_o$ the wave-particles scattering is described as single particle Compton scattering. As we will see later (Eq. (41)) the condition (12) is satisfied in our problem.

3. Transition probabilities

First we calculate the matrix elements for the nonlinear three wave interaction in the strongly magnetized electron-positron plasma when all three waves have their wave vectors along the magnetic field.

We represent the electric fields of the the three interacting waves in the form

$$\mathbf{E}(\mathbf{r},t) = \Re\left[\mathbf{E}_1 \exp\{i(\mathbf{k}_1\mathbf{r} - \omega_1 t)\} + \mathbf{E}_2 \exp\{i(\mathbf{k}_2\mathbf{r} - \omega_2 t)\} + \mathbf{E}_3 \exp\{i(\mathbf{k}_3\mathbf{r} - \omega_3 t)\}\right] \tag{13}$$

The indices $1, 2, 3$ refer to the scattered electromagnetic wave, plasma wave and the initial electromagnetic wave respectively, $\Re$ denotes the real part. We consider lineally polarized waves. For the parallel propagation the case of circularly polarized waves may be trivially reduced to the scattering of two lineally polarized waves. Implicit assumption here is that the coupling between the waves is weak, so that the waves retain their identity as eigenmodes of the medium during the times much longer than inverse of their frequencies.

We calculate transition probabilities by finding the coupling coefficients for the resonant three-wave interaction. The interaction of two transverse and one longitudinal wave propagating along magnetic field in a relativistic plasma has been considered by Brodin & Stenflo 1989. For the decay process $\omega_3 = \omega_1 + \omega_2$ and $k_3 = k_1 + k_2$ the coupling of the waves is described by the system of equations

$$\begin{aligned} \frac{dE_1}{dt} &= c_1 E_2^* \, E_3 \\ \frac{dE_2}{dt} &= c_2 E_1^* \, E_3 \\ \frac{dE_3}{dt} &= c_3 E_1^* \, E_3 \end{aligned} \tag{14}$$

where

$$\begin{aligned} c_1 &= -\frac{\omega_1^2}{\left(\frac{\partial \omega^2 \epsilon_{\pm}^{\perp}}{\partial \omega}\right)_1} C_{\pm} \\ c_2 &= -\frac{1}{\left(\frac{\partial \epsilon_{zz}}{\partial \omega}\right)_2} C_{\pm} \\ c_3 &= \frac{\omega_3^2}{\left(\frac{\partial \omega^2 \epsilon_{\pm}^{\perp}}{\partial \omega}\right)_3} C_{\pm} \end{aligned} \tag{15}$$

and

$$
\begin{aligned}
&\epsilon_{zz} = 1 + \sum \frac{\omega_p^2\, m}{k} \int \frac{d\mathbf{p}}{\omega - k v_z} \frac{\partial F(\mathbf{p})}{\partial p_z} \\
&\epsilon^{\perp}_{\pm} = 1 + \frac{1}{2} \sum \frac{\omega_p^2}{\omega^2} \int \frac{d\mathbf{p}}{\gamma} \left[\frac{(\omega - k v_z) p_\perp}{\omega - k v_z \mp \omega_c} \frac{\partial F(\mathbf{p})}{\partial p_\perp} + \frac{k\, p_\perp^2}{m\gamma(\omega - k v_z \mp \omega_c)} \frac{\partial F(\mathbf{p})}{\partial p_z} \right] \\
&C_{\pm} = - \sum \frac{\omega_p^2 q}{\omega_1 \omega_2 m} \int d\mathbf{p} \left\{ \frac{m}{\gamma \hat{\omega}_2} \frac{\partial F(\mathbf{p})}{\partial p_z} \right. \\
&\mp \frac{\partial}{\partial p_\perp^2} \left[\frac{\omega_c p_\perp^2}{\gamma^4 \hat{\omega}_2} \left(\frac{k_3}{(\hat{\omega}_1 \mp \omega_c)\,(\hat{\omega}_3 \mp \omega_c)} - \frac{k_1}{(\hat{\omega}_1 \mp \omega_c)(\hat{\omega}_3 \mp \omega_c)} - \frac{\gamma^2 v_z}{c^2} \frac{\hat{\omega}_1 + \hat{\omega}_3 \mp \omega_c}{\omega_1 \omega_3} \right) \right] F(\mathbf{p}) \\
&- \frac{p_\perp^2}{2\gamma^3 m c^2 \hat{\omega}_2} \left[1 - \frac{k_1 k_3 c^2}{\gamma^2 (\hat{\omega}_1 \mp \omega_c)\,(\hat{\omega}_3 \mp \omega_c)} - \right. \\
&\left. \left. v_z \left(\frac{k_3}{(\hat{\omega}_3 \mp \omega_c)} + \frac{k_1}{(\hat{\omega}_1 \mp \omega_c)} \mp \frac{\omega_c k_1}{(\hat{\omega}_1 \mp \omega_c)\, \hat{\omega}_2} \pm \frac{\omega_c k_3}{(\hat{\omega}_3 \mp \omega_c)\, \hat{\omega}_2} \right) \right] \times \frac{\partial F(\mathbf{p})}{\partial p_z} \right\}
\end{aligned}
\tag{16}
$$

where $\hat{\omega}_{1,2,3} = \omega_{1,2,3} - k_{1,2,3} v_z$ and $\omega_c = q B_0 / \gamma m c$ is the relativistic cyclotron frequency.

We now simplify this relations for the case of one dimensional pair plasma with the same distribution functions. Setting $F(\mathbf{p}) = \frac{1}{\pi} \delta(p_\perp^2) f(p_z)$ and introducing a positive nonrelativistic gyrofrequency $\omega_B = \sigma_q q B_0 / mc$ (σ_q is the sign of the charge) we find

$$
\epsilon_{zz} = 1 + \frac{2\omega_p^2}{k} \int \frac{dp_z}{\omega - k v_z} \frac{\partial f(p_z)}{\partial p_z} \tag{17}
$$

$$
\epsilon^{\perp} = 1 - 2\omega_p^2 \int \frac{dp_z}{\gamma} \frac{(\omega - k v_z)^2}{(\omega - k v_z)^2 - \omega_B^2/\gamma^2} f(p_z) \tag{18}
$$

$$
C = - \frac{2\omega_p^2 |q|}{\omega_1 \omega_3 m} \int \frac{dp_z}{\gamma^5} \frac{\omega_B}{\hat{\omega}_2^2} \left(\frac{k_3 \hat{\omega}_1}{\hat{\omega_1}^2 - \omega_B^2/\gamma^2} - \frac{k_1 \hat{\omega}_3}{\hat{\omega_3}^2 - \omega_B^2/\gamma^2} \right) f(p_z) \tag{19}
$$

The probability of the decay is (Melrose 1978c Eq. 10.124)

$$
\begin{aligned}
&u(\mathbf{k}_3, \mathbf{k_2}, \mathbf{k}_1) = (2\pi)^5 \hbar \frac{R_E^1 R_E^2 R_E^3}{\omega_3 \omega_1 \omega_2} \left| \omega_1 \omega_2 \omega_3 C \right|^2 \delta(\mathbf{k}_3 - \mathbf{k_2} - \mathbf{k}_1)\, \delta(\omega_3 - \omega_2 - \omega_1) = \\
&\frac{(2\pi)^5 \hbar q^2 \omega_p^4 \omega_B^2 \omega_2}{2 m^2 \omega_1 \omega_3} \left| \int \frac{dp_z}{\gamma^5 \hat{\omega}_2^2} \left(\frac{k_3 \hat{\omega}_1}{\hat{\omega_1}^2 - \omega_B^2/\gamma^2} - \frac{k_1 \hat{\omega}_3}{\hat{\omega_3}^2 - \omega_B^2/\gamma^2} \right) f(p_z) \right|^2 \\
&\delta(\mathbf{k}_3 - \mathbf{k_2} - \mathbf{k}_1)\, \delta(\omega_3 - \omega_2 - \omega_1)
\end{aligned}
\tag{20}
$$

with $R_E^1 = R_E^2 = R_E^3 = 1/2$

In the cold case we have

$$u(\mathbf{k}_3, \mathbf{k_2}, \mathbf{k}_1) = \frac{(2\pi)^5 \hbar q^2 \omega_p^4 \omega_B^2}{2m^2 \omega_1 \omega_3 \omega_2^3} \left| \frac{k_3 \omega_1}{\omega_1^2 - \omega_B^2} - \frac{k_1 \omega_3}{\omega_3^2 - \omega_B^2} \right|^2 \delta(\mathbf{k}_3 - \mathbf{k_2} - \mathbf{k}_1)\, \delta(\omega_3 - \omega_2 - \omega_1) \tag{21}$$

which may be obtained from Melrose 1978c Eq. 10.105.

Equations (17) and (19) can be simplified in the limit of a very strong magnetic field. In the limit $\hat{\omega} \ll \omega_B/\gamma$ we find

$$\epsilon^{\perp} = 1 + \frac{2\omega_p^2}{\omega_B^2} \int dp_z \gamma (\omega - k v_z)^2 f(p_z) \tag{22}$$

$$C = \pm \frac{2\omega_p^2 |q|}{m} \int \frac{dp_z}{\gamma^3} \frac{1}{\hat{\omega}_2^2 \omega_B} \left(\frac{k_3}{\omega_3} - \frac{k_1}{\omega_1} \right) f(p_z) \tag{23}$$

Using Eq. (17) the equation (23) may be rewritten in the form

$$C = \pm \frac{2|q|}{m\omega_B} \left(\frac{k_3}{\omega_3} - \frac{k_1}{\omega_1} \right) (\epsilon_{zz} - 1) \tag{24}$$

For the back scattering Eq. (23) gives

$$C \approx \pm \frac{2|q| k_2}{\omega_{1,3} \omega_B m} (\epsilon_{zz} - 1) \tag{25}$$

For the plasma waves on the mass surface $\epsilon_{zz} = 0$ and

$$\begin{aligned} C &= \pm \frac{2|q| k_2}{\omega_{1,3} \omega_B m} \\ u(\mathbf{k}_3, \mathbf{k_2}, \mathbf{k}_1) &= \frac{2^2 q^2 k_2^2 (2\pi)^5 \hbar}{m^2 \omega_B^2} \omega_2 \delta(\mathbf{k}_3 - \mathbf{k_2} - \mathbf{k}_1)\, \delta(\omega_3 - \omega_2 - \omega_1) \end{aligned} \tag{26}$$

We can compare this probability with the unmagnetized case (Tsytovich 1970). In the strongly magnetized plasma the probability of Raman scattering is decreased by a ratio $\omega_{1,3}^2/\omega_B^2$. This is similar to the suppression of the Thompson scattering, whose probability is decreased by the same ratio.

It is convenient to describe the wave distribution in terms of photon occupation numbers

$$n_{\mathbf{k}} = \frac{E_{\mathbf{k}}^2}{\hbar\omega(\mathbf{k})} \tag{27}$$

where $E_{\mathbf{k}}^2$ is the spectral energy density, which is related to the total energy density

$$W = \int \frac{d\mathbf{k}}{(2\pi)^3} E_{\mathbf{k}}^2 \tag{28}$$

The kinetic equation for the Raman scattering are (Melrose 1978c, Eq. (5.93))

$$\begin{aligned}
\frac{dn_1(\mathbf{k}_1)}{dt} &= -\int \frac{d\mathbf{k}_3}{(2\pi)^3} \int \frac{d\mathbf{k}_2}{(2\pi)^3} u(\mathbf{k}_3, \mathbf{k}_1, \mathbf{k}_2) \left(n_1(\mathbf{k}_1) n_2(\mathbf{k}_2) - n_3(\mathbf{k}) \left(n_1(\mathbf{k}_1) + n_2(\mathbf{k}_2)\right)\right) \\
&\quad + \Gamma_3 n_3(\mathbf{k}_3), \qquad (29) \\
\frac{dn_2(\mathbf{k}_2)}{dt} &= -\int \frac{d(\mathbf{k}_1)}{(2\pi)^3} \int \frac{d\mathbf{k}_3}{(2\pi)^3} u(\mathbf{k}_3, \mathbf{k}_1, \mathbf{k}_2) \left(n_1(\mathbf{k}_1) n_2(\mathbf{k}_2) - n_3(\mathbf{k}_3) \left(n_1(\mathbf{k}_1) + n_2(\mathbf{k}_2)\right)\right) \\
&\quad + \Gamma_2 n_2(\mathbf{k}_2), \qquad (30) \\
\frac{dn_3(\mathbf{k}_3)}{dt} &= \int \frac{d(\mathbf{k}_1)}{(2\pi)^3} \int \frac{d\mathbf{k}_2}{(2\pi)^3} u(\mathbf{k}_3, \mathbf{k}_1, \mathbf{k}_2) \left(n_1(\mathbf{k}_1) n_2(\mathbf{k}_2) - n_3(\mathbf{k}_3) \left(n_1(\mathbf{k}_1) + n_2(\mathbf{k}_2)\right)\right) \\
&\quad + \Gamma_3 n_3(\mathbf{k}_3) \qquad (31)
\end{aligned}$$

Where $\Gamma_{1,2,3}$ are the corresponding damping or growth rates. The most unimportant damping is the Landau damping of the plasma waves $n_2(\mathbf{k}_2)$ on the particles of plasma. In (31) the total derivative on the left hand side is

$$\frac{d}{dt} = \frac{\partial}{\partial t} + \frac{\partial \omega}{\partial \mathbf{k}} \frac{\partial}{\partial \mathbf{r}} - \frac{\partial \omega}{\partial \mathbf{r}} \frac{\partial}{\partial \mathbf{k}} \tag{32}$$

with the second term describing the convective transport of the waves.

Next we integrate over transverse wave vectors to find the system of equations describing the scattering of the waves propagating along magnetic field

$$\frac{dn_1(k_1)}{dt} = -\int \frac{dk_2}{(2\pi)} \int \frac{dk_3}{(2\pi)} u(k_2, k_1, k_2) \left(n_1(k_1) n_2(k_2) - n_3(k_3) \left(n_1(k_1) + n_2(k_2)\right)\right)$$

$$
\begin{aligned}
&\quad +\Gamma_1 n_1(k_1), &(33)\\
\frac{dn_2(k_2)}{dt} &= -\int \frac{dk_1}{(2\pi)}\int \frac{dk_3}{(2\pi)} u(k_2,k_1,k_2)\left(n_1(k_1)n_2(k_2) - n_3(k_3)\left(n_1(k_1)+n_2(k_2)\right)\right)\\
&\quad +\Gamma_2 n_2(k_2), &(34)\\
\frac{dn_3(k_3)}{dt} &= \int \frac{dk_1}{(2\pi)}\int \frac{dk_2}{(2\pi)} u(k_2,k_1,k_2)\left(n_1(k_1)n_2(k_2) - n_3(k_3)\left(n_1(k_1)+n_2(k_2)\right)\right)\\
&\quad +\Gamma_3 n_3(k_3) &(35)
\end{aligned}
$$

where

$$n_i(k_i) = \int \frac{d^2 k_{i,\perp}}{(2\pi)^2} n_i(\mathbf{k}_i), \qquad i = 1,2,3 \tag{36}$$

and

$$u(k_2,k_1,k_2) = \frac{2^2 q^2 k_2^2 (2\pi)^5 \hbar\omega_2}{m^2\omega_B^2}\delta(k_3-k_2-k_1)\,\delta(\omega_3-\omega_2-\omega_1) \tag{37}$$

The two δ-functions in $u(k_2,k_1,k_2)$ allow us to perform integrations in (35).

$$
\begin{aligned}
\frac{dn_1(k_1)}{dt} &= -\frac{2^2 q^2 k_2^2 (2\pi)^3 \hbar\omega_2}{m^2\omega_B^2\left(\frac{\partial\omega_3}{\partial k_3}\right)}\left(n_1(k_1)n_2(k_2) - n_3(k_3)\left(n_1(k_1)+n_2(k_2)\right)\right) + \Gamma_1 n_1(k_1), &(38)\\
\frac{dn_2(k_2)}{dt} &= -\frac{2^2 q^2 k_2^2 (2\pi)^3 \hbar\omega_2}{m^2\omega_B^2\left(\frac{\partial\omega_1}{\partial k_1}\right)}\left(n_1(k_1)n_2(k_2) - n_3(k_3)\left(n_1(k_1)+n_2(k_2)\right)\right) + \Gamma_2 n_2(k_2), &(39)\\
\frac{dn_3(k_3)}{dt} &= \frac{2^2 q^2 k_2^2 (2\pi)^3 \hbar\omega_2}{m^2\omega_B^2\left(\frac{\partial\omega_2}{\partial k_2}\right)}\left(n_1(k_1)n_2(k_2) - n_3(k_3)\left(n_1(k_1)+n_2(k_2)\right)\right) + \Gamma_3 n_3(k_3) &(40)
\end{aligned}
$$

Implicit assumption in Eqs. (38) - (40) is that the wave vectors on the right hand side of Eqs. (38), (39) and (40) satisfy the resonance conditions. Thus in Eq. (38), for example, the two independent variables are time t and wave vector k_1. The explicit relations between wave vectors, corresponding to Eqs. (38), (39) and (40), are

$$k_3 \approx k_2 = 2T^2|k_1| + k_o, \qquad \omega_2 = (2T^2|k_1| + k_o - 2|k_1|)c$$

$$
\begin{aligned}
|k_1| &= \frac{k_2 - k_o}{2T^2}, \qquad k_3 \approx k_2, \qquad \omega_2 = (k_2 - \frac{k_2 - k_o}{T^2})c \\
|k_1| &\approx \frac{k_3 - k_o}{2T^2}, \qquad k_2 \approx k_3, \qquad \omega_2 = (k_3 - \frac{k_3 - k_o}{T^2})c
\end{aligned}
\tag{41}
$$

respectively for Eqs. (38), (39) and (40). The quantity $k_o = \sqrt{2T}\omega_p$ is the cross-over wave vector, where the dispersion relation for the plasma waves intersect the vacuum dispersion relation.

From Eqs. (41) and (12) we find that the induced Raman scattering occurs in the frequency region

$$
\sqrt{2T}\omega_p \leq kc \leq 2\sqrt{2T}\omega_p \tag{42}
$$

This frequency window (in the plasma frame) corresponds to the frequencies in the pulsar frame in the range $2\sqrt{T\lambda\omega_B\Omega/\gamma_p} \leq kc \leq 4\sqrt{T\lambda\omega_B\Omega/\gamma_p}$, which is $5 \times 10^8 \mathrm{rad\,sec}^{-1} \leq kc \leq 10^9 \mathrm{rad\,sec}^{-1}$ which falls into the observed frequency range.

4. Application to Pulsars

In this section we consider the possible applications of the induced Raman scattering to the wave propagation and spectrum formation in the pulsar magnetospheres.

4.1. Scattering of the Pump Wave

There is threshold intensity of the pump wave that defines what is known as strong induced Raman scattering. The rate of induces plasmon production, which depends on the intensity of the pump wave, should exceed the rate of loss due to the various damping processes. The end result of such strong scattering is a total depletion of the initial pump wave. The threshold photon density for strong Raman scattering is determined from (39)

$$
\int \frac{dk_1}{2\pi} \int \frac{dk_3}{2\pi} u(k_3, k_1, k_2) n_3(k_3) = \Gamma_2 \tag{43}
$$

where Γ_2 is the damping rate of plasma waves.

Linear Landau damping rate in the relativistic plasma ($T_p \gg 1$) is (Lyutikov 1998

$$\Gamma_2 = \frac{\pi \omega_p^4}{T k c \omega^2} \left(\gamma^3 \frac{\partial f}{\partial \gamma} \right)_{res} \tag{44}$$

with

$$\gamma_{res}^2 = \frac{k_0 T_p^2}{\Delta k}, \qquad k_0 c = \omega_0 = \sqrt{2 T_p} \omega_p, \qquad \Delta k = k - k_0 \tag{45}$$

The equations are valid for $\Delta k \leq k_0$.

With a power law distribution function $f \propto \gamma^{-\alpha}$, $\alpha > 2$ we find

$$\Gamma_2 \approx \frac{\pi \omega_p}{T_p^{3/2}} \left(\frac{k_0 T_p^2}{\Delta k} \right)^{-\alpha/2+1} \tag{46}$$

Note that as $\Delta k \to 0$, i.e. when the wave vector approaches the cross-over point where the phase speed is equal to the speed of light, $\Gamma_2 \to 0$ since there no particles with the speed equal to the speed of light.

The threshold spectrum of the incoming radiation is then given by

$$n_3 \approx \frac{m^2 c^3 T^{-\frac{2+5\alpha}{4}}}{64 \pi^2 \hbar q^2} \frac{\omega_B^2}{\omega_p^2} \left(\frac{\Delta k c}{\omega_p} \right)^{-1+\alpha/2} \tag{47}$$

Estimating $\Delta k \approx k_o$ we find the characteristic threshold photon density:

$$n_3^{th} \approx 10^{-2} \frac{m^2 c^3 \omega_B^2}{q^2 \hbar \omega_p^2} T^{-1-\alpha} = 2.7 \times 10^{22} \; \frac{1}{cm^2} \, B_{12} \, \lambda_5^{-1} \, P_{0.2} \, T_{10}^{-3} \, R_9^{-3} \gamma_{p,10} \tag{48}$$

where $B_{12} = B/10^{12}$G is a magnetic field at the surface of the neutron star, $\lambda_5 = \lambda/10^5$ is the multiplicity factor, i.e. the ratio of the plasma density to the Goldreich-Julian density $n_{GJ} = \mathbf{\Omega} \cdot \mathbf{B}/(2\pi e c)$, $P_{0.2} = P/0.2$sec is the pulsar period, $T_{10} = T/10$ is the relativistic invariant temperature, $R_9 = R/10^9$cm is the distance from the neutron star, $\gamma_{p,10} = \gamma_p/10$ is the average streaming Lorentz factor of the secondary plasma and we used $\alpha = 2$. Note, that this is an *upper* bound on the threshold photon density (for $k \approx 2k_o$). At the lower frequencies $k \approx k_o$ the threshold values are much lower.

For the relativistic Gaussian-type distribution $f \propto 1/T \times \exp\{-\gamma/T\}$ the damping rate is

$$\Gamma_2 \approx \left(\frac{\omega_p}{\Delta k c}\right)^{3/2} \frac{\omega_p}{T^{3/4}} \exp\left\{-\left(\frac{2\omega_p^2 T}{\Delta k^2\, c^2}\right)^{1/4}\right\} \tag{49}$$

(compare with Lominadze & Mikhailovskii 1978 Eq. (2.10)). The spectrum of the incoming radiation is then given by

$$n_3 \approx \frac{m^2 c^3 \omega_B^2}{128\pi^2 q^2 \hbar T^{9/4} \omega_p^2} \left(\frac{\Delta k c}{\omega_p}\right)^{-3/2} \exp\left\{-\left(\frac{2\omega_p^2 T}{\Delta k^2\, c^2}\right)^{1/4}\right\} \tag{50}$$

The characteristic threshold photon density is in this case

$$n_3^{th} \approx 10^{-4} \frac{m^2 c^3 \omega_B^2}{q^2 T^3 \hbar \omega_p^2} = 5 \times 10^{-5} \frac{m^2 c^3 \omega_B \gamma_p}{q^2 T^3 \hbar \Omega \lambda} = 2.7 \times 10^{20} \;\; \tfrac{1}{cm^2}\, B_{12}\, \lambda_5^{-1}\, P_{0.2}\, T_{10}^{-3}\, R_9^{-3} \gamma_{p,10} \tag{51}$$

(upper bound) where we used $\omega_p^2 = 2\omega_B \Omega \lambda/\gamma_p$.

For the comparable values of the temperature, i.e. for the similar dispersion of the energies of the plasma particles, the threshold in the case of a power law distribution is much larger than in the case of Maxwell-type distribution. This is due to the larger damping rate in the case of a power law distribution since there are more particles satisfying the Cherenkov resonance in this case than in the case of Maxwell-type distribution.

The estimates (48) and (51) are done for the one dimensional (in **k**) photon density in the plasma frame. The photon densities (48) and (51) are the one dimensional photon densities.

The energy flux per unit interval of frequencies is given in terms of photon density as follows:

$$F(\nu) d\nu = \frac{n(\mathbf{k}, \mathbf{r}) c \hbar \omega d\mathbf{k}}{8\pi^3} = \frac{n(k, \mathbf{r}) c \hbar \omega dk}{2\pi} = n(k, \mathbf{r}) \hbar \omega d\nu \tag{52}$$

Where we took into account that the dispersion relation of the electromagnetic waves is almost vacuum like, so $k \approx \omega/c$.

We recall next, that both three dimensional occupation numbers $n(\mathbf{k},\mathbf{r})$ and one dimensional photon density $n(k,\mathbf{r})$ (Eq. (refkd921)) are relativistic invariants. It follows from (52) that

$$\frac{F(\nu)}{\nu} = \mathrm{inv} \tag{53}$$

(for the one dimensional flux, i.e. integrated over transverse wave vectors). Thus, the flux in the observer frame is

$$F'(\nu') = 2\pi n(k',\mathbf{r})\hbar\nu' \text{ in } \frac{\mathrm{erg}}{\mathrm{cm}^2\,\mathrm{sec}\,\mathrm{Hz}} \tag{54}$$

We can estimate the observed flux (in Jankys) at the Earth:

$$F^{\mathrm{obs}}(\nu') = F'(\nu')\left(\frac{R}{d}\right)^2 \tag{55}$$

Using Eqn. (48), (51), (54) and (55) we find

$$F^{\mathrm{obs}} = \begin{cases} \frac{10^{-2}}{T^{1+\alpha}} \\ \\ \frac{10^{-4}}{T^3} \end{cases} \times \frac{\pi m^2 c^3 \omega_B^* \gamma_p \nu}{q^2 \Omega \lambda} \left(\frac{R_{NS}}{d}\right)^2 \left(\frac{R_{NS}}{R}\right) \tag{56}$$

for the power law and exponential distributions correspondingly.

Numerical estimates give

$$F^{\mathrm{obs}} = \begin{pmatrix} 30 \\ \\ 3\times 10^{-1} \end{pmatrix} \mathrm{Jy} \tag{57}$$

These are comparable with the fluxes observed from bright pulsars. Since the estimated threshold intensities are upper bounds, we conclude that stimulated Raman scattering may be an important factor in the formation of pulsar radio emission. Estimates for the millisecond pulsars give about an order of magnitude lower values.

4.2. Saturation of Cyclotron Instability by the Induced Raman Scattering

Cyclotron-Cherenkov instability, operating in the outer parts of magnetosphere at the anomalous Doppler resonance

$$\omega(\mathbf{k}) - k_{\|} v_{\|} - s \frac{\omega_B}{\gamma} = 0 \quad \text{for } s < 0 \tag{58}$$

has been suggested as a possible mechanism of pulsar radio emission (Kawamura & Suzuki 1977, Lominadze, Machabeli & Mikhailovskii 1979, Kazbegi et al. 1991b, Lyutikov 1998). In this section we consider the nonlinear saturation of the cyclotron-Cherenkov instability by the induced Raman Scattering. To simplify the consideration, we assumes that the product electromagnetic waves (labeled by index 1) leave the region of resonant interaction, so we can assume that their photon density is $n_1(k_1) \approx 0$. We are interested in the time asymptotic limit for the intensities of the transverse waves, excited by some instability mechanism with a growth rate Γ_3. Neglecting the wave convection we then find from Eqs. (38) and (40):

$$\frac{2^2 q^2 k_2^2 (2\pi)^3 \hbar \omega_2}{m^2 \omega_B^2 \left(\frac{\partial \omega_1}{\partial k_1}\right)} n_3(k_3) + \Gamma_2 n_2(k_2) = 0, \tag{59}$$

$$-\frac{2^2 q^2 k_2^2 (2\pi)^3 \hbar \omega_2}{m^2 \omega_B^2 \left(\frac{\partial \omega_2}{\partial k_2}\right)} n_2(k_2) + \Gamma_3 n_3(k_3) = 0 \tag{60}$$

Comparing Eqs. (43) and (59) we find that they are identical: the threshold intensity for the strong Raman scattering is equal to the saturation intensity. This is not a surprising fact, since in both cases it is the damping of the plasma waves that controls the electromagnetic wave intensity. In Section 4.1 we found that the corresponding intensities are comparable to the observed ones, so that the nonlinear saturation by the induced Raman scattering may provide an observed emissivities.

We also note in this context, that at a given radius, the induced Raman scattering operates in a limited frequency range (12). So, if the instability that produces radio emission is intrinsically broad band (with the bandwidth of the growing mode larger than the range in which the induced Raman scattering operates), then the effects of the induced Raman scattering would produce a dip in the spectrum, corresponding to that frequency range. If, on the other hand, the instability that produces radio emission is intrinsically narrow band with the central frequency of the instability falling into the operational range of the induced Raman scattering and changing with radius to mimic the observed broadband spectrum, then the induced Raman scattering can be an effective saturation mechanism for a larger range of frequencies.

5. Conclusion

In this work we considered induced Raman scattering of a transverse electromagnetic wave propagating along magnetic field in a pair plasma. We found that induced Raman scattering can be an important factor for the wave propagation in the pulsar magnetosphere and as a nonlinear saturation mechanism for the electromagnetic instabilities (cyclotron-Cherenkov instability, for example). The threshold intensities for strong Raman scattering, which are determined by the damping rate of the Langmuir waves in the relativistic plasma, are comparable to the observed fluxes from radio pulsars.

One of the major limitations of this work is the assumption of the propagation along the magnetic field. The natural extension of this work to oblique propagation would involve several complications: (i) there will be a distinction in the transition probabilities between extraordinary mode (with the electric field of the waves perpendicular to the $\mathbf{k}-\mathbf{B}$ plane) and ordinary mode (with the electric field in the $\mathbf{k}-\mathbf{B}$ plane), (ii) ordinary mode has an sensitive dependence on the angle of propagation, so that for the ordinary mode the Raman scattering will occur only in a very limited angle around magnetic field; the scattered waves will be a backward propagating, (iii) for the extraordinary mode the Raman scattering is possible for large angles of propagation; in this case both electromagnetic waves can be forward propagating.

I would like to thank Roger Blandford, Peter Goldreich and Gia Machabeli for their useful comments.
